During speech, the tongue is able to move both laterally and medially, usually to create a 'bridge' of tissue that spans across the

palate. This results in the production of a palatal click sound. The relation between muscle activity and tongue movement has been examined extensively in vivo, but there is little published work on the formation of the tissue bridge and the relation between tongue movement and muscle activity in a living subject. We therefore employed the technique of SORBONNE et al. (1986) to monitor palatal muscle activity and to record tongue movement during consonantal production in an awake subject. The mandibular constrictor muscle was used to control the shape of the palate in order to reveal the pattern of muscle activity and tongue movement that would form a 'bridge'. We found that the muscles on the lateral side of the tongue produce the lateral component of movement that forms the bridge. These muscles also show a correlation between their electrical activity and tongue movement, which is particularly strong at the onset of movement. The muscles on the medial side of the tongue, including the mylohyoid and geniohyoid muscles, were found to produce a bridge of tissue on both the dorsal and the ventral surfaces of the palate 5b5f913d15
