Assessment of insulin resistance: the clinician's perspective. Insulin resistance and hyperglycemia are most often associated with type 2 diabetes mellitus and should be considered in the evaluation of any patient with impaired glucose tolerance or hyperglycemia. The vast majority of patients with type 2 diabetes mellitus have evidence of insulin resistance. Clinical assessment of insulin resistance includes calculation of the insulin sensitivity by methods such as the euglycemic-hyperinsulinemic clamp or the minimal model method. However, these methods are technically difficult and require laboratories equipped with special equipment and expertise. An alternative and less expensive method involves the use of the homeostasis model assessment (HOMA), where the reciprocal of plasma insulin and plasma glucose are multiplied to give an estimate of the insulin sensitivity. Several studies have compared the precision and reliability of these methods with the invasive euglycemic-hyperinsulinemic clamp. HOMA appears to be the best-validated surrogate index of insulin resistance, with sensitivity and specificity >85%. Although the euglycemic-hyperinsulinemic clamp is the gold standard, there are practical problems associated with its use. For example, it has been shown that individuals taking oral hypoglycemic medications may require a higher-than-normal dose of insulin to achieve euglycemia. Insulin resistance is a common feature of diseases such as obesity and noninsulin-dependent diabetes mellitus, and clinicians should recognize that the presence of insulin resistance can predispose patients to the

The present invention relates to integrated circuits, and more particularly, to a technique for accessing and testing memory elements in a non-volatile memory integrated circuit. Non-volatile memories, such as Flash Memories, are used in a variety of different applications and devices. For example, a personal computer or other data processing device may include a Flash Memory or other non-volatile memory for storage of various data and other information. In addition, cellular telephones, personal digital assistants (PDAs), and other devices may include Flash Memory, for storage of various data, such as telephone numbers, calendar information, user ID's, passwords, and other types of information. A typical Flash memory cell includes a source, a drain, and a channel positioned between the source and drain. A non-volatile memory such as a Flash Memory is constructed by forming a plurality of Flash memory cells on a single substrate. Each memory cell includes a source, a drain, a floating gate, and a control gate electrode. A current representing stored data is drawn through the drain of the memory cell when data is stored in the memory cell. During a programming operation, charge is injected onto the floating gate of the memory cell to place the memory cell into a programmed state. During a reading operation, current drawn through the drain of the memory cell represents the data stored in the memory cell. A typical Flash memory has both a programming and erase operation that includes erasing and programming all memory cells in an array. Some non-volatile memories such as Flash Memories include a spare row or other redundant row of memory cells. For example, a Flash Memory typically includes one or more spare rows of memory cells that can be used to replace defective memory cells in the primary rows. When a defective primary row is detected, a redundant bit line column of memory cells is substituted for the defective primary row. The redundant bit line column of memory cells is generally identical to the defective primary row, but is included in the memory integrated circuit in an additional region. Defective primary memory cells are generally detected using a built-in self-test circuit within the integrated circuit. Defective memory cells may also be detected by measuring the amount of current drawn from the main supply voltage, VDD, by the defective memory cells. Some non-volatile memory integrated circuits include a configuration, referred to as d0c515b9f4.

Movavi Video Converter 19.3.0 Serial key This invention relates to an optical anode for an X-ray generator, and, more particularly, to an X-ray generator having an optical anode. A typical X-ray generator is illustrated in FIG. 1. X-rays are produced when electrons, accelerated to very high energies, strike a metal target. The X-rays are then directed through an analyzing device to perform an analytical function, such as, for example, X-ray fluorescence. The analyzing device may consist of a fluorescent screen and a plate having a fluorescent layer on the side facing the screen. The energy of the X-rays is typically from a few tenths of a keV to several tens of keV. For X-ray analysis, a detector is required that is capable of detecting X-rays with the lowest possible dose. For the detection of X-rays with the lowest dose it is typically necessary to limit the X-ray input to the tube to a level below which the target in the tube would be damaged. The focus of the X
